## SECTION 1

### SCOPE

#### 1.1 INTRODUCTION

The NASA GSFC Landsat-D Project is developing a Data Management System (DMS) to provide a variety of standard image products from the thematic mapper (TM) and multispectral scanner (MSS) instruments. The major digital image processing functions to be performed by the DMS include: screening imagery for quality, determining cloud cover, applying radiometric corrections, computing sets of geometric corrections corresponding to different map projections, and applying a set of geometric corrections (including resampling the data using either cubic convolution or nearest neighbor techniques and presenting the data in either a space oblique mercator, universal transverse mercator, or polar stereographic projection). One of the outputs from the DMS is partially processed MSS data (radiometric corrections applied and geometric correction matrices for two projections appended) which is recorded on HDT-AM tapes. An HDT-AM is a 28-track or 14-track high density tape.

This specification establishes the requirements for the format of the Landsat-D HDT-AM product. These requirements represent both derived and allocated requirements from the GSFC Specification for the Landsat-D System, GSFC-430-D-100B.

This document is part of the Landsat-D Data Format Control Book. It is one of several appendices to Volume VI, which describe the format of Landsat-D and Landsat-D Prime products.

ORIGINAL PAGE IS  
OF POOR QUALITY

## 1.2 PURPOSE

The purpose of this document is to define the format of the HDTs which contain partially processed Landsat-D and D Prime MSS image data. This format is based on and is compatible with the existing format for partially processed Landsat-3 MSS image data HDTs (as delineated in IPF ICD-201).

This document and those cited in Section 2 provide complete specification of the HDT-AM data format and should be followed in utilizing and interpreting the format of these tapes.

## 1.3 APPLICABILITY

This document applies to all Landsat-D and D Prime partially processed MSS data tapes recorded by the DMS as an output of initial image processing and to all copies of all or parts of these tapes. The formats for the HDTs which contain partially and fully processed Landsat-D Prime TM data are defined in other Data Format Control Book Appendices (HDT-AT in Appendix A, GES 10033; HDT-PT in Appendix B, GES 10034).

### SECTION 3

#### PRODUCT DESCRIPTION

##### 3.1 RECORDED-DATA FORMATS

Partially processed Landsat-D and D Prime MSS data and IRIG-A time code data will be recorded on HDT-AM tapes utilizing Martin-Honeywell Model No. 2879-L high density digital tape recorders. The formatting performed by these recorders (i.e., track assignments, packing density, framing, randomizing, and error correction capability) are specified in the Data Format Control Book, Volume VI: Products (reference paragraph 2.2.b). This appendix does not include any reference to the recorder formatting process.

##### 3.2 TAPE FORMAT

Each HDT-AM tape is arranged in band sequential (BSQ) format. A 14-track HDT-AM can contain up to about 45 scenes, while a 28-track HDT-AM can contain up to about 180 scenes (the absolute maximum capacities are about 25% larger). In order to facilitate transfer of data from 28-track to 14-track tapes, the data on a physical 28-track tape is blocked in "logical" HDT-AM tapes, where each portion of the data known as a "logical" HDT-AM tape will fit onto a single 14-track tape. In actual practice a logical is restricted to a maximum of about 34 scenes due to the hardware configuration used to generate the tapes. There is no restriction on the minimum number of scenes in a logical. However, there will always be only one logical on a physical 14-track HDT-AM tape, and no more than five logicals on a physical 28-track HDT-AM tape. Integral scenes will not be divided between logical tapes.

ORIGINAL PAGE IS  
OF POOR QUALITY

Each logical HDT-AM tape contains a tape directory appearing at the beginning, followed by data in the following order for each band of each scene: header, ancillary, annotation, preamble/filler, image, trailer, and more preamble/filler (see Figure 3.2-1). Due to the starting and stopping of HDT-AM tapes which will occasionally be necessary during their generation, data gaps will occur. They will appear only between scenes and usually will occupy only a few inches of tape.

### 3.2.1 TIME CODE

The HDT-AM contains a longitudinal time track (with time monotonically increasing) on auxiliary track number 1 that provides an index to the location of image data on the HDT. The time is recorded in the IRIG-A format (reference paragraph 2.2.a) and has a time resolution of 1/10th of a second. The ten-character time code provides hundreds, tens, and units of the day of the year; tens and units of hours; tens and units of minutes; and tens, units, and tenths of seconds. The time code gives the universal time at which the data was recorded on the original HDT-AM tape and is used to correlate image data to sequential position on the HDT (for example on the CHIT). The time code may be discontinuous between data intervals and during data gaps. All other regions of the tape, including preamble/filler, will have time code recorded.

### 3.2.2 MAJOR FRAME CONVENTIONS

All the information on the tape is organized into major frames. Every major frame is 3232 bytes in length and is divided into eight minor frames of equal size. These values are constant for all parts of all HDT-AM tapes, in no case

ORIGINAL PAGE IS  
OF POOR QUALITY

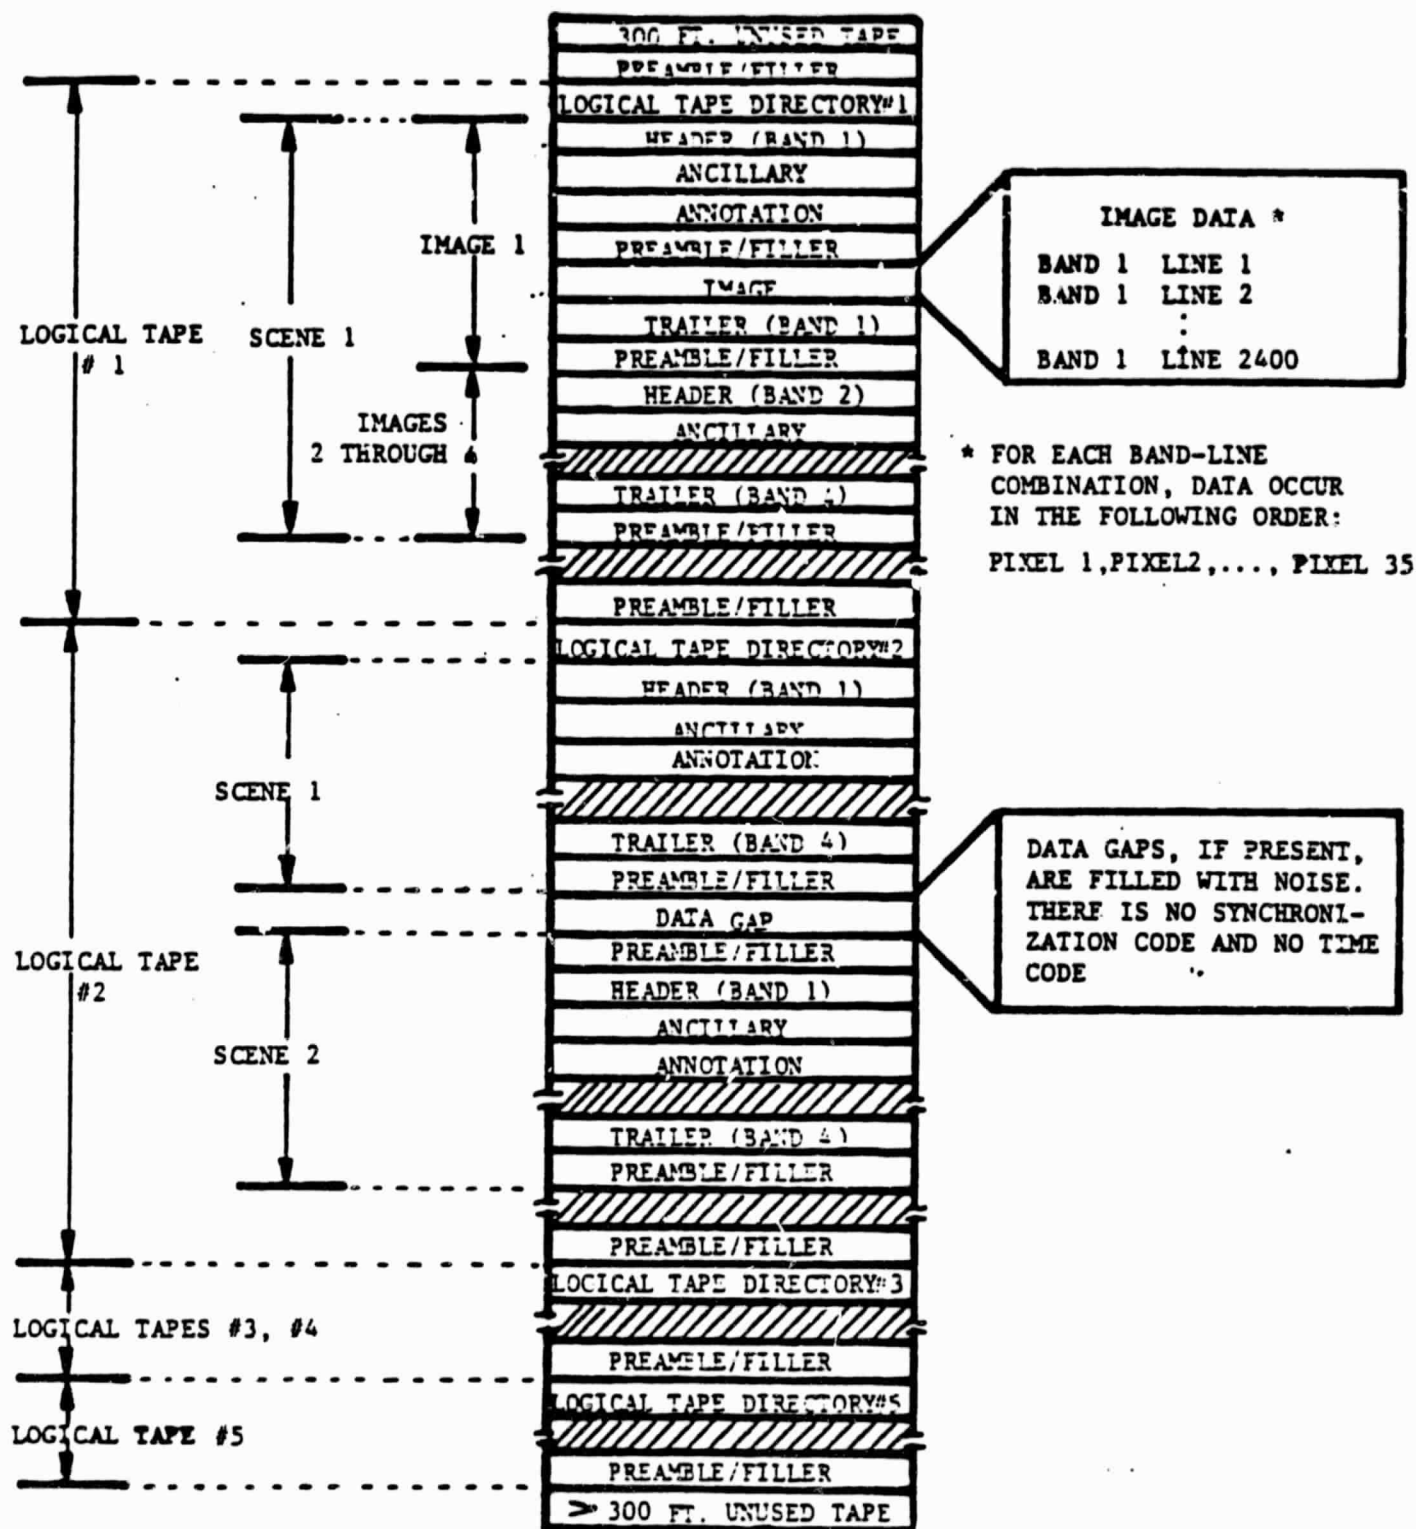

Figure 3.2-1. Layout of an HDT-AM

**ORIGINAL PAGE IS  
OF POOR QUALITY**

will partial major or minor frames occur. The sequence of the major frames on the tape is shown in Figure 3.2-2.

Approximately 3000 major frames of preamble/filler precede each logical tape directory. The logical tape directory is one major frame long. Following each logical tape directory is a set of scenes, each one containing four images.

Each image consists of:

- 1 major frame of header data
- 26 major frames of ancillary data
- 2 major frames of annotation data
- 158 major frames of preamble/filler
- 2400 major frames of image data
- 1 major frame of trailer data.

Between each image in a scene and between the last image in one scene and the first image in the next scene there will be more than 350 major frames of preamble/filler. Figure 3.2-3 shows the spacing and data relationships. In cases where data gaps occur, greater than 350 major frames of preamble/filler will precede the gap and approximately 3000 major frames of preamble/filler will follow the gap.

For all types of major frames except preamble/filler and image data a parameter called the CHECKSUM is computed. The four-byte (32-bit) CHECKSUM is computed on 32-bit segments of data commencing at the boundary between the minor frame type

ORIGINAL PAGE IS  
OF POOR QUALITY

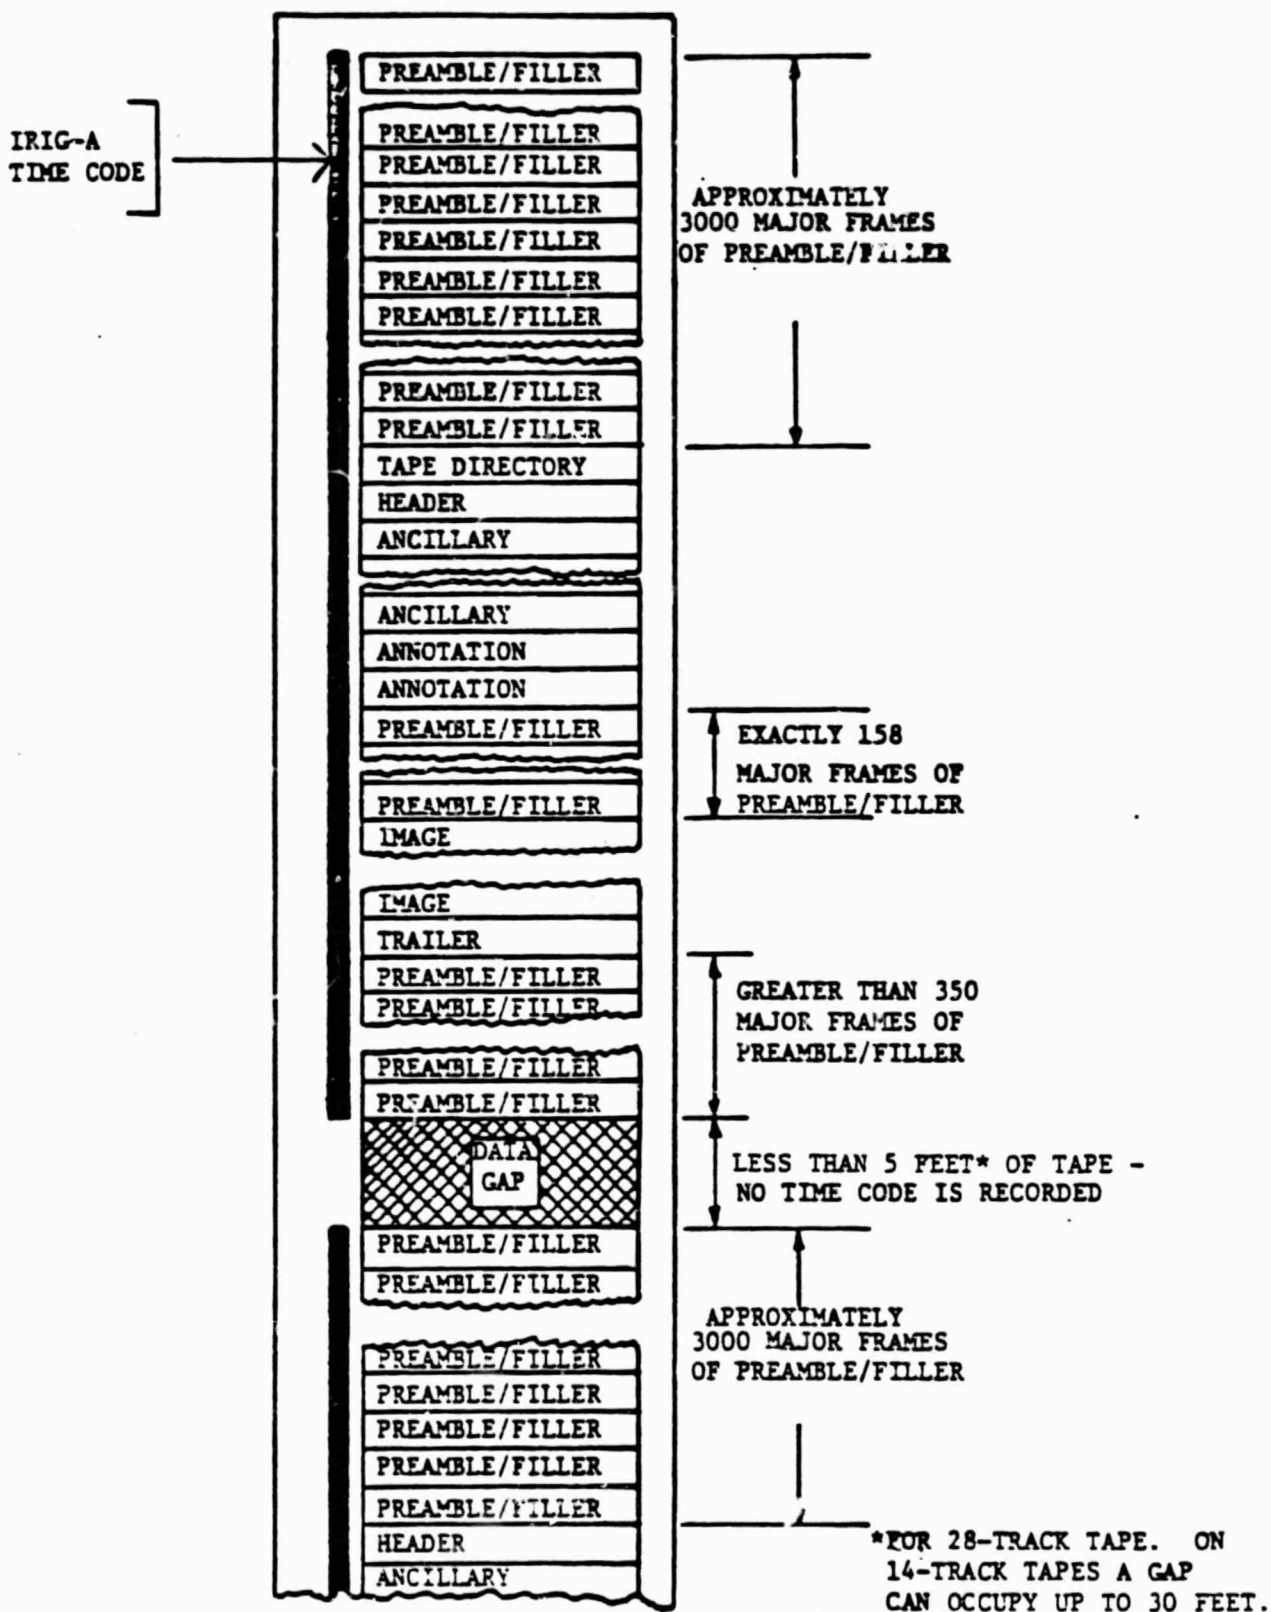

Figure 3.2-2. Symbolic Illustration of the Time Code Track and Other Recorded Data

ORIGINAL PAGE IS  
OF POOR QUALITY

ORIGINAL PAGE IS  
OF POOR QUALITY

code and the alphanumeric data; that is, the six bytes (48 bits) of standard identification information at the beginning of each minor frame are not included in the computation of the CHECKSUM. The CHECKSUM is placed in the major frame following the data fields, the specific location is indicated in the description of each major frame type (paragraph 3.3). The CHECKSUM computation is performed only on the data which precedes it in the major frame (i.e., trailing zero fill is not included).

The CHECKSUM, for a series of data bytes, is computed by performing successive EXCLUSIVE ORs (XOR) between the four bytes of CHECKSUM and a four byte data block, followed by a CHECKSUM bit rotation. The computation is equivalent to the following set of procedural steps:

CHECKSUM = 0

DO FOR I = 1 to N (where 4N is the number of bytes to be checked)

CHECKSUM = CHECKSUM XOR DATA(I)

CHECKSUM = ROTATE (CHECKSUM, 1 BIT LEFT)

ENDDO

where ROTATE means:

ORIGINAL PAGE 13  
OF POOR QUALITY

### 3.2.3 MINOR FRAME CONVENTIONS

Every minor frame is 404 bytes in length for all EDT-AM tapes. The 398-byte data field is preceded by six bytes of standard information: four bytes of frame synchronization, one byte of minor frame count, and one byte of minor frame type code. In addition to the standard information the data field in image type minor frames is preceded by six bytes of scan line identification (SLID). Therefore, image minor frames will contain 12 bytes of standard information and 392 bytes of (pixel) data.

#### 3.2.3.1 Frame Synchronization

A 32-bit pattern, 11 111 010 111 100 110 011 010 000 000 000 (FAF3 3400 HEX), repeated at the beginning of every minor frame, provides frame synchronization. The most significant bit occurs first and is the left-most bit of the pattern. In figures depicting major frames this pattern is referred to as the SYNC pattern.

#### 3.2.3.2 Minor Frame Count

Within each major frame the binary minor frame count starts at zero and continues in sequence until its value equals seven. Under no circumstance is the minor frame count reset to zero or any other number until the end of the major frame.

#### 3.2.3.3 Minor Frame Type Code (MFTC)

The minor frame type code is a number that defines the type of data within a minor frame. Each minor frame contains one of seven types of information. The

ORIGINAL PAGE IS  
OF POOR QUALITY

MFTC byte consists of two identical three-bit data words ( $W_1 = W_2$ ), and two identical one-bit parity words ( $P_1 = P_2$ ) which provide single-bit-error-correcting capabilities. The codes used are:

DATA TYPE	HEXADECIMAL VALUE	OCTAL VALUE	BINARY REPRESENTATION								
Preamble/Filler	C0	300	1	1	0	0	0	0	0	0	0
Tape Directory	09	011	0	0	0	0	1	0	0	1	
Header	12	022	0	0	0	1	0	0	1	0	
Annotation	DB	333	1	1	0	1	1	0	1	1	
Ancillary	24	044	0	0	1	0	0	1	0	0	
Image	ED	355	1	1	1	0	1	1	0	1	
Trailer	F6	366	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>0</u>	
			$P_1$	$P_2$			$W_1$			$W_2$	

Where:

$W_1$  = three-bit MFTC word number 1

$W_2$  = three-bit MFTC word number 2

$P_1$  = parity bit for  $W_1$

$P_2$  = parity bit for  $W_2$

#### 3.2.3.4 Data Representations

In addition to binary coded data and information in standard ASCII format, four special formats, detailed in the following paragraphs, are utilized to represent fixed and floating point numbers. In all cases the order of the bytes is as shown, that is, no byte-swapping is performed.

##### 3.2.3.4.1 Fixed Point Binary Format (FP)

This format is used in ancillary major frames 1 and 2 and in the header and

ORIGINAL PAGE 13  
OF POOR QUALITY

trailer major frame. A number is represented in four bytes, as follows:

FIXED POINT BINARY FORMAT (FP)

BIT 31 — S(SIGN) = 0(+), 1(-)  
BITS 30:0 — MAGNITUDE

NOTE: Negative numbers (sign bit = 1) are represented in two's complement form.

### 3.2.3.4.2 Floating Point Binary Format (FL)

This format is used in ancillary major frames 1 and 2 and in the trailer major frame. This format is also commonly called the long precision (double word) format. A number is represented in eight bytes, as follows:

FLOATING POINT BINARY FORMAT (FL)

BIT 63 — S(SIGN) = 0(+), 1(-)  
BITS 62:56 — EXPONENT, RANGE OF -64 THROUGH +63. TREATED AS EXCESS 64.  
BITS 55:0 — FRACTION MAGNITUDE, 14 HEXIDECIMAL DIGITS. THE VALUE IS FOUND BY MULTIPLYING THE FRACTIONAL PART BY THE POWER OF 16.

ORIGINAL PAGE IS  
OF POOR QUALITY

NOTE: The FL format does not utilize two's complement notation.

3.2.3.4.3 Single Precision Floating Point Binary Format (FLS)

This format is used in ancillary major frames 1 and 2 and in the header major frame. A number is represented in four bytes, as follows:

SINGLE PRECISION FLOATING POINT BINARY FORMAT (FLS)

BIT 31 → S(SIGN)=0(+), 1(-)

BITS 30:24 → EXPONENT, RANGE OF -64 THROUGH +63. TREATED AS EXCESS 64.

BITS 23:0 → FRACTION MAGNITUDE, 6 HEXIDECIMAL DIGITS. THE VALUE IS FOUND BY MULTIPLYING THE FRACTIONAL PART BY THE POWER OF 16.

NOTE: The FLS format does not utilize two's complement notation.

ORIGINAL PAGE IS  
OF POOR QUALITY

3.2.3.4.4 Fixed Point Format for HRS Grid Pixels, VRS Line Coordinates, or Grid Fill Counts

This format is used in ancillary major frames 3 through 18. A number is represented in four bytes, as follows:

GRID PIXEL, GRID LINE COORDINATE, OR GRID FILL COUNT FORMAT

BIT 31  $\rightarrow$  (SIGN)=0(+), 1(-)  
BITS 30:18  $\rightarrow$  INTEGER MAGNITUDE  
BITS 17:0  $\rightarrow$  FRACTION MAGNITUDE

NOTE: Negative numbers (sign bit = 1) are represented in two's complement form (of the integer and fraction field together).

3.3 MAJOR FRAME TYPES

3.3.1 PREAMBLE/FILLER

Preamble/filler is placed on a tape primarily to ensure the proper operation of the recorder in the playback mode and to separate each image. Each minor frame of preamble/filler begins with the six bytes of standard identification data (sync pattern, minor frame count, and minor frame type code) and is completed

ORIGINAL PAGE IS  
OF POOR QUALITY

with the preamble/filler pattern, which consists of alternating 1's and 0's (101010101010...). This pattern is repeated until the complete major frame is filled, as shown in Figure 3.3-1.

### 3.3.2 TAPE DIRECTORY DATA

The logical tape directory consists of one major frame containing an alphanumeric description of the "logical" tape. The description contains information such as the logical HDT identification number, date of generation, etc. Each minor frame of the tape directory begins with the six bytes of standard identification information, followed by the tape description and zero fill. A major frame of tape directory is shown in Figure 3.3-2. Table 3.3-1 lists specific items that are found in the tape directory. A tape directory appears at the beginning of the tape; on a 28-track high density tape additional tape directories may appear, splitting the data into multiple "logical" HDT-AM tapes. Each "logical" HDT-AM tape fits onto a single 14-track high density tape. Scenes are not divided between logical tapes.

The correlation between the external tape label and the logical tape identifier is as follows for various circumstances:

- a. For an original 28-track HDT the tape label is the same as the identifier of the first logical on that physical tape.
- b. For 14-track HDTs (which are all copied from 28-track HDTs) the tape label is the same as the the logical identifier.
- c. A whole tape copy will have a tape label which is identical to the tape label of its parent except it will contain a "C" to indicate that it is a copy.

Table 3.3-1. Logical Tape Directory Data Elements

A. Tape Identification

<u>BYTES</u>	<u>DATA</u>	<u>DESCRIPTION</u>
1 - 2	L N	<u>Logical Tape Identification</u> - contains 20 ASCII bytes of tape identification:
3 - 4	M H	"L" = Landsat mission designator N = Mission Number (4 for Landsat-D, 5 for Landsat-D', 0 for these logicals containing both Landsat-D and D Prime)
5 - 6	A Y	"M" = MSS sensor type
7 - 8	Y D	"HA" = Tape type designator for HDT-A
9 - 10	D D	YY = Last two digits of year (00-99)
11 - 12	X X	DDD = Day of year (001-366) on which original HDT-AM tape was generated
13 - 14	Y Y	XX = Unique identifier (1-99) for each logical generated on day DDD
15 - 16	Y Y	Y = blank
17 - 18	Y Y	
19 - 20	Y Y	
21 - 22	Day Mon	<u>Date of Tape Generation</u> - contains the date in binary, where Yr is the last two digits of the year. (For a copy tape this contains the date the original was generated.)
23	Yr	
24	XXXX	<u>Source of HDT-AM production</u> - hardware string used to generate tape: 001) <sub>8</sub> = MIPS #1 002) <sub>8</sub> = MIPS #2 003) <sub>8</sub> = MIPS #3
25 - 40	X X	<u>Software Version Number</u> - 16 ASCII bytes
41 - 44	XXXX XXXX XXXX XXXX	CHECKSUM value for bytes 1-40 of Tape Directory
45 - 398	000 000	Zero Fill (not used)

ORIGINAL PAGE IS  
OF POOR QUALITY

The part of the tape directory which contains the generation date will not be changed during the copy process, it will always contain the date on which the original was generated.

### 3.3.3 BAND HEADER DATA

The band header contains information associated with a particular band of image data. This information describes the conditions under which the image was recorded and the formats used. Figure 3.3-3 illustrates a major frame of header data.

Header data are subdivided into five groups:

- a. Image identification
- b. Spacecraft description
- c. Time of exposure and WRS designator
- d. Data identification and characteristics
- e. Special purpose fields.

The data elements of these groups are listed in Table 3.3-2. Unless otherwise noted, all alphanumeric data in the header is ASCII encoded and all numerical "counts" are encoded in binary.

### 3.3.4 ANCILLARY DATA

The ancillary data provides geometric correction information which enables partially processed imagery to be fully processed at a later date, i.e., to go

ORIGINAL PAGE IS

**Table 3.3-4. Overall Band Quality Codes  
(byte 146 in Header Data Section)**

The assessment of the overall quality of a band of imagery is based on the combined geometric, radiometric, and image data quality. The codes are calculated as follows

Code	Relative Quality	Geometric* Correction Quality Code	Radiometric* Correction Quality Code	Image* Data Quality Code
C	<div style="text-align: center;">Best</div>  <div style="text-align: center;">Acceptable</div>	E	E	E
B		E	E	G
A		E	G	E
9		G	E	E
8		E	G	G
7		G	E	G
6		G	G	E
5		G	G	G
4		A	E	E
3		A	E	G
2		A	G	E
1		A	G	G
0		A	E or G or A	A
0		A	A	E or G or A

\* E=EXCELLENT  
G=GOOD  
A=ACCEPTABLE

The Geometric Correction Quality Code is defined in Table 3.3-5.  
The Radiometric Correction Quality Code is defined as follows:

$$\begin{aligned}
 0 &\leq RCA \leq 1.0 \Rightarrow E \\
 1.0 &< RCA \leq 2.0 \Rightarrow G \\
 2.0 &< RCA \Rightarrow A
 \end{aligned}$$

Where RCA is the Relative Calibration accuracy as defined in bytes 149 through 152 of the header.

The Image quality Code is defined as follows

$$\begin{aligned}
 0 &\leq DQI \leq 1.5 \Rightarrow E \\
 1.5 &< DQI \leq 4.5 \Rightarrow G \\
 4.5 &< DQI \Rightarrow A
 \end{aligned}$$

Where DQI is defined as  $DQI = \text{Major frame synch losses} + \text{Minor Frame synch losses}/20 + \text{Unrecoverable ECC count errors}/20$

ORIGINAL PAGE IS  
OF POOR QUALITY

Table 3.3-5. Overall Geometric Assessment Quality Codes  
(Byte 226 in Header Data Section)

The assessment of the overall quality of the geometric modeling process is based upon the number and distribution of control points used. The code actually represents the number of parameters modeled in the Geometric Correction Data processing. The code can take on the following values:

Code	Parameters Modeled	Overall Band Quality Code
0	none, correction is SCD only	A
2	Along track, across track (control points used to calculate translation errors)	G
4	Along track, across track, yaw, altitude	E
6	Along track, across track, yaw, altitude, along track rate, across track rate	E

ORIGINAL PAGE IS  
OF POOR QUALITY

from a geometrically uncorrected array of pixels to a geometrically corrected array of pixels. A total of 26 major frames of ancillary data constitute the ancillary data section. A generalized major frame of ancillary data is illustrated in Figure 3.3-4. The ancillary major frames contain information in the following order:

- a. Two major frames of geometric modeling data
- b. Eight major frames of UTM or PS (depending on image latitude) map projection dependent data
- c. Eight major frames of SON map projection dependent data, in the same format as the previous eight major frames
- d. Eight major frames of zero fill.

3.3.4.1 Geometric Modeling Data

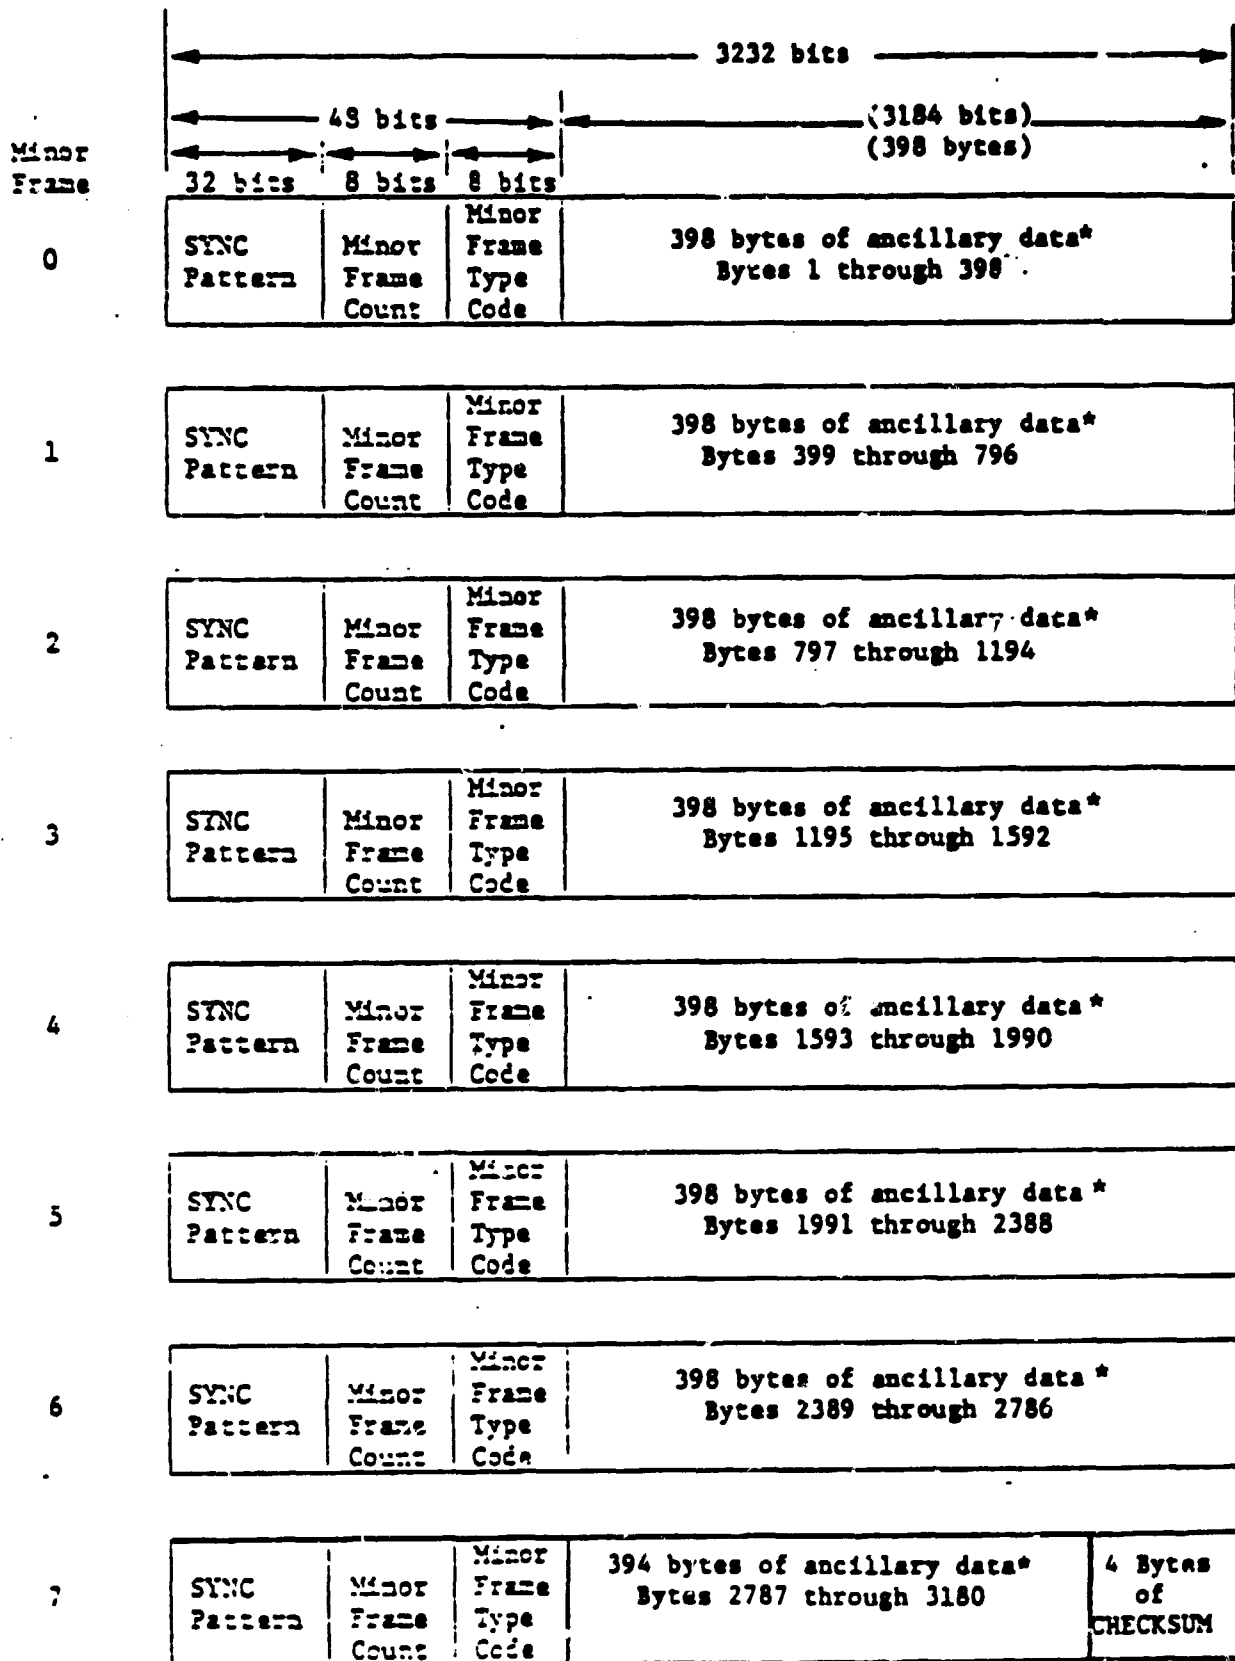

As indicated above, the first two major frames of ancillary data contain geometric modeling data. The data elements that comprise this section are delineated in Table 3.3-6. The first major frame contains a set of "universal" spacecraft constants, the values of these constants are given in Table 3.3-7. The second major frame contains spacecraft parameters related to the individual scene.

A discussion of the geometric correction process is given in Data Format Control Book, Volume VI, Products (reference paragraph 2.2.b).

3.3.4.2 Projection Data

Major frames 3 through 10 support either the UTM or PS map projection and are

logically coupled to the first major frame of annotation data. Major frames 11 through 18 support the SOM map projection and are logically coupled to the second major frame of annotation data. Major frames 19-26 are zero filled and reserved as spares. Byte 118 in the header (Table 3.3.-2) designates the projection type (PS or UTM) found in major frames 3 through 10. Each set of eight projection data major frames contains the following information:

- a. Horizontal Resampling (HRS) grid. The HRS grid is a 51 by 61 element array that defines input pixel number as a function of position in hybrid space. The HRS values are biased by half the nominal line length plus one, and are therefore zero at nominal midscan - 12444 bytes.
- b. Vertical Resampling (VRS) grid. The VRS is a 44 by 61 element array that defines input line number as a function of position in output space. The VRS values are biased by the number of sweeps prior to scene center in the useful data. This bias is stored in NSWEEPS (bytes 3165-3166) in Ancillary major frames 10 and 18) - 10736 bytes.
- c. 51 Left fill counts 204 bytes
- d. 51 Right fill counts 204 bytes
- e. Pixel number of WRS center 2 bytes
- f. WRS offset from image center 2 bytes
- g. Temporal registration scene identification 20 bytes
- h. Corners of temporally registered area 32 bytes
- i. Location of image overlap marks 16 bytes
- j. Actual number of tick marks 4 bytes

### 3.3.5 ANNOTATION DATA

Two structurally identical major frames of annotation data follow the ancillary section, one complete major frame for each map projection - UTM or PS (as indicated in byte 118 in the header) - followed by SOM. When the framed image data covers sites north of  $65^{\circ}\text{N}$  latitude or south of  $65^{\circ}\text{S}$  latitude, PS values are given in place of UTM values. Each major frame contains both the alphanumeric information printed at the bottom of a film product and information about the tick marks which surround the fully processed framed image. Figure 3.3-7 illustrates the location of both the annotation and the tick mark information relative to the fully processed image writing area, independent of map projection.

An example of a major frame of annotation is given in Figure 3.3-8. The first minor frame of annotation data, containing the 115 bytes of annotation data that is printed at the bottom of a film product, is fully illustrated in Table 3.3-9 and Figure 3.3-9. The data content of the next six minor frames is limited to the tick marks that surround the fully processed image. An example of a major frame of annotation is given in Figure 3.3-9.

Pixel 1, scan line 1 in the fully processed image is the point to which all tick mark information is referenced. Each tick mark is located approximately 1000 meters from the fully processed image area. The exact distances, measured from the center of the edge pixel in the image area to the tick mark, are: 997.5 meters (17.5 pixels) on the bottom and right sides and 1054.5 meters (18.5 pixels) on the top and left sides. Figure 3.3-10 illustrates tick mark features and their utilization in a fully processed (i.e., geometrically corrected)

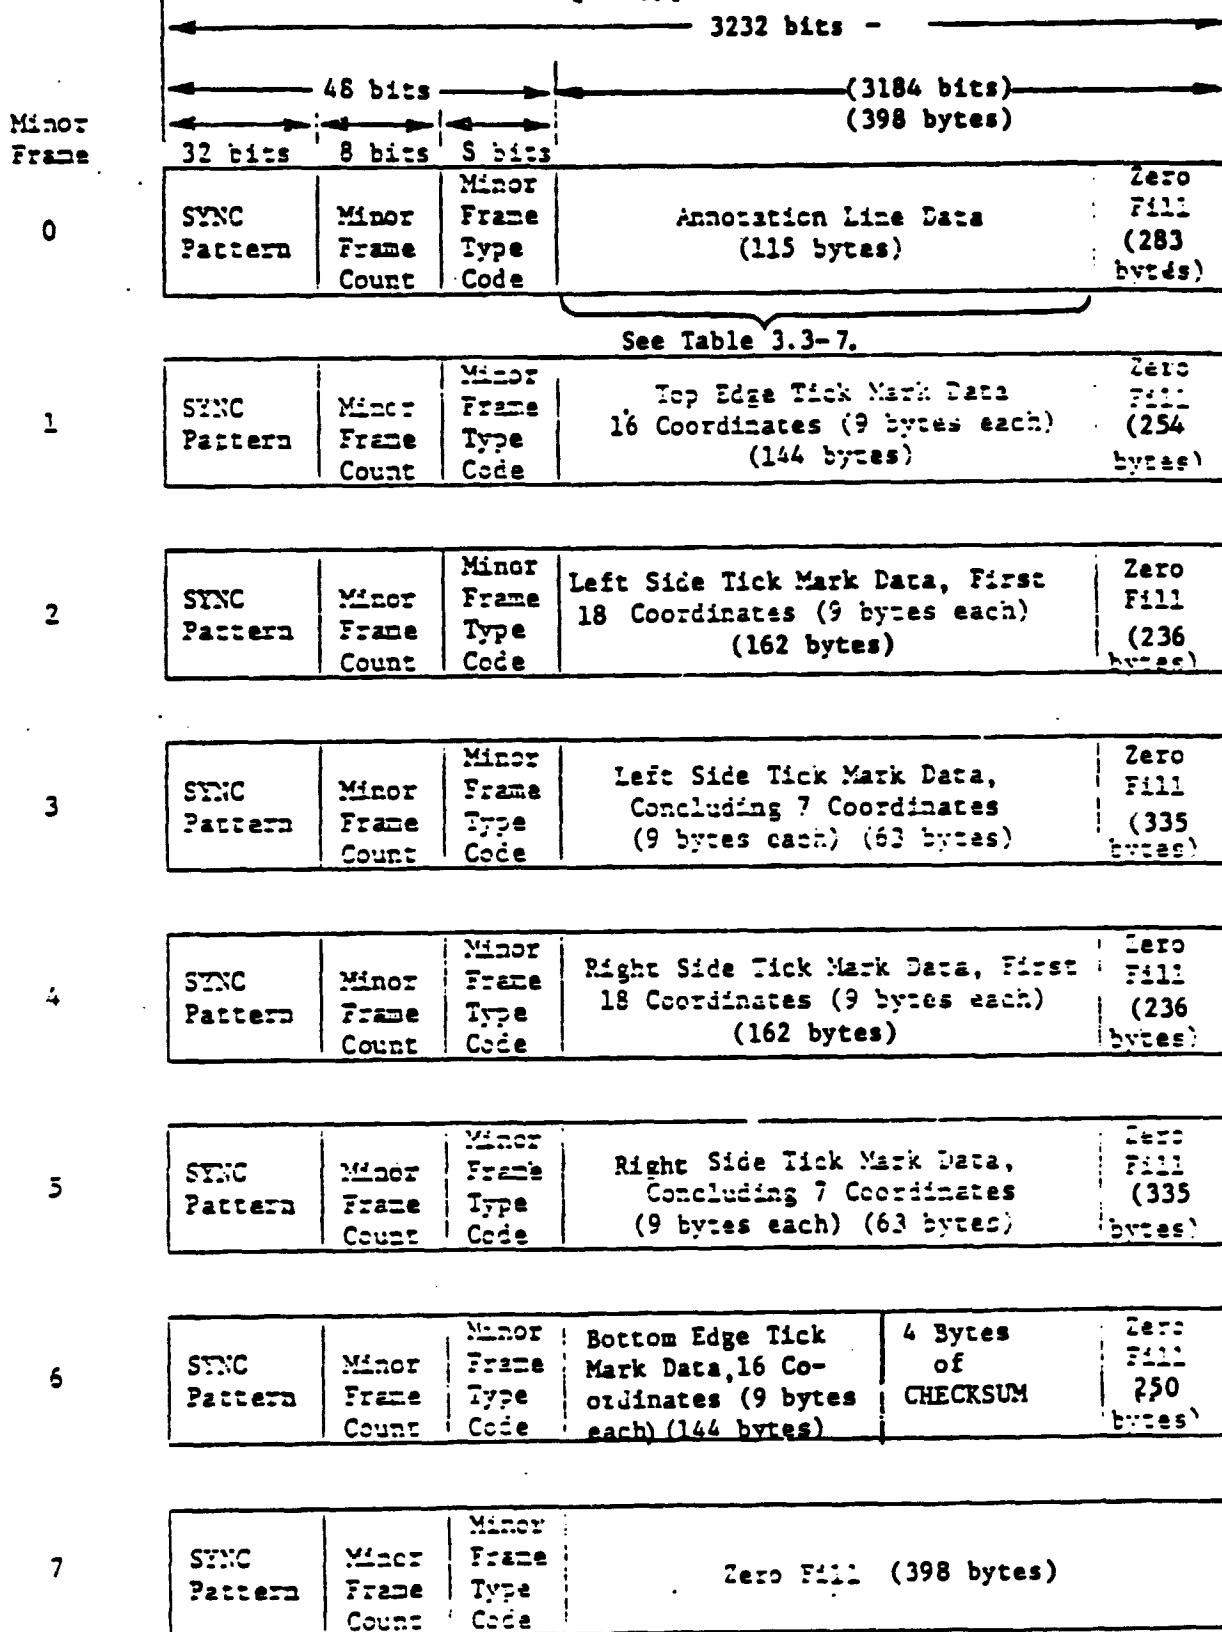

Figure 3.3-8. One Major Frame of Annotation

Table 3.3-9. Detailed Explanation of the 115  
Character Annotation Field  
(Also see Figure 3.3-9.)

FIELD	CHARACTER POSITION	EXAMPLE	EXPLANATION
a	01 - 08	07JUN82Y	Day, month and year of image acquisition
b	09 - 25	C6N33-05/W115-18Y	Image Format Center - Latitude and longitude of the center of the MSS image format in degrees and minutes.
c	26 - 34	D202-101Y	WRS path and row identifier and orbital direction indicator. The "D" indicates spacecraft is descending, an "A" indicates spacecraft is ascending. The 202 is path number and 101 is row number.
d	35 - 51	N6N33-03/W115-42Y	WRS center latitude and longitude
e	52 - 61	M61234YWDY	Sensor (MSS) and spectral band identification code. There are separate characters for each band, this example shows the position of each band identifier; normally only one character is present. The "D" indicates direct transmission from the spacecraft (not stored on-board before transmission).
f	62 - 75	SUNVEL30YA015Y	Sun Angles - the sun elevation angle and sun azimuth angle measured clockwise from true North at time of midpoint of MSS frame is specified to the nearest degree. Blank for ascending node coverage.
g	76 - 87	U6P-6D-N6L2Y	PROCESSING CODES (These codes apply to the geometric correction matrix values and to the final geometrically corrected image data.) Character position 76 defines the type of geometric correction applied to the data: "U" = uncorrected "S" = system level corrected "G" = geometrically corrected based on geodetic information (no temporal registration performed) "T" = temporal registration using geodetic information from a single reference scene "R" = temporal registration to a single reference scene (no geodetic information available)
	76		
	78		Character position 78 defines the projection: "P" = Polar stereographic projection "S" = Space Oblique mercator projection "U" = Universal Transverse Mercator projection

ORIGINAL PAGE IS  
OF POOR QUALITY

Table 3.3-9. Detailed Explanation of the 115  
Character Annotation Field (cont'd)

FIELD	CHARACTER POSITION	EXAMPLE	EXPLANATION
	80		Character position 80 indicates the resampling algorithm; always blank for geometrically uncorrected data.
	81		Character position 81 indicates the type of ephemeris data used to compute the geometric correction matrices. "P" = predictive "D" = definitive "G" = GPS
	83		Character position 83 gives the processing procedure: "N" = normal processing procedure "A" = abnormal processing procedure
	85		Character position 85 indicates the sensor gain: "H" = high gain "L" = low gain
	86		Character position 86 shows the type of MSS transmission: "1" = linear mode "2" = compressed mode
h	88 - 100	NASA/LANDSAT	Identifies the Agency and the Project
i	101 - 115	E-N1042-16032-1	Frame identification number - each image or frame will have a unique identifier which will contain encoded information consisting primarily of time of acquisition (Universal Time) relative to launch. Its format is E-NDDDD-HHMMSS-B and is interpreted as follows: "E" = Encoded Project Identifier N = Landsat Mission Number  DDDD = Day number, relative to launch, at time of observation HH = Hour at time of observation MM = Minute at time of observation  S = Tens of seconds at time of observation B = Band identification code (MSS): 1, 2, 3, 4

image. As shown at the bottom of Figure 3.3-10, the most significant bit in the binary tick mark location bytes specifies the placement and format of the coordinate data. Specifically, a "0" signifies the annotation is either below or to the right of the tick mark with trailing blanks and a "1" signifies the annotation is either above or to the left of the tick mark with leading blanks. Tick mark annotation examples for each of the map projections are provided in Figure 3.3-11.

In the annotation major frame, space has been reserved for 16, 25, 25, and 16 tick marks on the top, left, right and bottom sides respectively. In actual practice no more than ten tick marks will be provided on each of the four sides, in minor frames one, two, four, and six. Within each of these minor frames the tick mark data is left justified (with respect to the minor frame) and all unused data fields will be zero filled. The concluding minor frame (number seven) is zero filled. The order of tick mark data, both in appearance in the respective minor frame and on the image product, is summarized below:

TICK MARK ZONE	ORDER OF APPEARANCE
Top	Left to right
Left	Top to bottom
Right	Top to bottom
Bottom	Left to right

### 3.3.6 IMAGE DATA

The image data section contains the radiometrically corrected image data as well

ORIGINAL PAGE IS  
OF POOR QUALITY

UTM Tick Mark (ASCII Notation)

X	X	N E	0	3	5	8	8	8
---	---	--------	---	---	---	---	---	---

3 blanks (trailing blank format)

Coordinate - ranges from 000 to 995 in increments of 5; scale factor is  $10^4$  m (therefore, value shown represents 350,000m)

Either N for Northing (sides) or E for Easting (top and bottom)

Binary Location of the Tick Mark:  
Either Pixel Number for Top or Bottom Edge  
or Line Number for Left or Right Side

NOTE: LEADING BLANK FORMAT IS AS IN FIGURE 3.3-10.

Polar Stereographic Tick Mark (ASCII Notation)

X	X	X Y	+ -	0	3	5	8	8
---	---	--------	--------	---	---	---	---	---

2 blanks (trailing blank format)

Coordinate - same as in UTM

Quadrant Sign of Coordinate

Either X or Y, both can appear on any edge

Binary Location of Tick Mark - same as in UTM

NOTE: LEADING BLANK FORMAT IS SIMILAR TO FIGURE 3.3-10.

Figure 3.3-11. Tick Mark Annotation

ORIGINAL PAGE IS

as quality and calibration information. Each major frame of image data contains all the pixels in a scan line from a single detector. All minor frames of image data (as shown in Figure 3.3-12) begin with six eight-bit bytes of standard identification information: sync pattern, minor frame count, and minor frame type code. This field is followed by a 48-bit scan line identification (SLID) that uniquely identifies each scan line. Thus, each minor frame of image data has the first 96 bits reserved for identification information. The SLID format is shown in Figure 3.3-13. Specifically, it contains the spacecraft time, a band indicator, and a binary count. The 40-bit spacecraft time updates every alternate mirror sweep (or every 12 major frames). To provide the unique scan line(major frame) identification, a four-bit count is utilized. The count starts at one and is incremented by one every major frame until the binary count reaches 12. The first scan line in an image is always from detector one and has a count of one.

As shown in Figure 3.3-12, space for up to 3548 seven-bit pixels is provided in each major frame (448 pixels in minor frames 0 through 6 and 412 pixels in minor frame 7). Compressed pixels will have been decompressed into seven-bit pixels. Six-bit pixels received in the linear mode have a zero as the MSB.

For Landsat-D and D Prime, two options are available to determine the gain and bias values for each detector which are then used to radiometrically calibrate the input image data. The first uses the calibration wedge while the second uses histograms of image data. Byte 147 in the header indicates which option was used. The support data for each image data major frame contains both sets of gain and offset values (see Table 3.3-10). A discussion of the radiometric

as quality and calibration information. Each major frame of image data contains all the pixels in a scan line from a single detector. All minor frames of image data (as shown in Figure 3.3-12) begin with six eight-bit bytes of standard identification information: sync pattern, minor frame count, and minor frame type code. This field is followed by a 48-bit scan line identification (SLID) that uniquely identifies each scan line. Thus, each minor frame of image data has the first 96 bits reserved for identification information. The SLID format is shown in Figure 3.3-13. Specifically, it contains the spacecraft time, a band indicator, and a binary count. The 40-bit spacecraft time updates every alternate mirror sweep (or every 12 major frames). To provide the unique scan line (major frame) identification, a four-bit count is utilized. The count starts at one and is incremented by one every major frame until the binary count reaches 12.

As shown in Figure 3.3-12, space for up to 3548 seven-bit pixels is provided in each major frame (448 pixels in minor frames 0 through 6 and 412 pixels in minor frame 7). Compressed pixels will have been decompressed into seven-bit pixels. Six-bit pixels received in the linear mode have a zero as the MSB.

For Landsat-D and D Prime, two options are available to determine the gain and bias values for each detector which are then used to radiometrically calibrate the input image data. The first uses the calibration wedge while the second uses histograms of image data. Byte 147 in the header indicates which option was used. The support data for each image data major frame contains both sets of gain and offset values (see Table 3.3-10). A discussion of the radiometric

Table 3.3-10. Support Data Elements

Image Line Supporting Data Word	7 Bit Data Word*	Description
1-4	1 1 1 1 1 1 1	"1" fill bits
5	0 $X_{11}X_{10}X_9X_8X_7X_6$	Original Line Length: $X_{11}$ through $X_0$ represents the
6	0 $X_5X_4X_3X_2X_1X_0$	actual number of pixels in the original geometrically uncorrected image scan line.
7	0 X X X X X X	Quality Code (See Figure 3.3-14)
8	0 $X_1X_2X_3X_4X_5X_6$	Nominal Cal. Indicator: Contains a 1 bit for each Calibration Wedge substitution; example: 000100 indicates that sample #4 was replaced by a nominal value.
9	0 X X X X X X (CWV #1)	Selected Cal. Wedge Values (CWVs)
10	0 X X X X X X (CWV #2)	Six binary numbers; one for
11	0 X X X X X X (CWV #3)	each Calibration Wedge sample.
12	0 X X X X X X (CWV #4)	Binary Values ranging from
13	0 X X X X X X (CWV #5)	0 to 63) <sub>10</sub> .
14	0 X X X X X X (CWV #6)	
15	0 0 0 0 0 0 X	Time Code Indicator: Contains a 1 bit if time code in SLID was calculated (i.e., was not obtained from video data stream)
16 - 20	0 0 0 0 0 0 0	Unused. "0" fill bits
21	0 0 0 $X_{15}X_{14}X_{13}X_{12}$	Cal. Wedge Gain Value: $X_{15}$ through $X_0$ represent the
22	0 0 0 $X_{11}X_{10}X_9X_8$	16-bit binary number applied
23	0 0 0 $X_7X_6X_5X_4$	in the radiometric correction
24	0 0 0 $X_3X_2X_1X_0$	process. Each value has a fixed binary point between positions $X_{10}$ and $X_9$ .
25	0 0 0 $X_{15}X_{14}X_{13}X_{12}$	Cal. Wedge Bias Value: $X_{15}$ through $X_0$ represent the
26	0 0 0 $X_{11}X_{10}X_9X_8$	16-bit binary number ** applied in
27	0 0 0 $X_7X_6X_5X_4$	the radiometric correction process.
28	0 0 0 $X_3X_2X_1X_0$	Each value has a fixed binary point between positions $X_2$ and $X_1$ .
29-32		Histogram Gain Value: Same format as Cal. Wedge Gain Value
33-36		Histogram Bias Value: Same format as Cal. Wedge Bias Value

\*Left most bit of each data word is a "0" fill bit

\*\*Negative numbers (bit 15 = 1) are represented in two's complement form (of  
the integer and fraction field together).

calibration options is given in Data Format Control Book, Volume VI: Products (reference paragraph 2.2.b). The calibration wedge option was utilized by all previous Landsats. The multiplicative and additive constants which are also used in the calibration process are given in bytes 3001-3048 in the second ancillary major frame.

It should be pointed out that because of computational roundoffs and occasional dual entries in the decompression tables the radiometric calibration process is not uniquely reversible.

A fixed number of fill pixels (with a value of 0)<sub>10</sub> are inserted in each major frame in front of the image pixels. The fill count is different for each band:

Band 1	75 Fill Pixels
Band 2	73 Fill Pixels
Band 3	71 Fill Pixels
Band 4	69 Fill Pixels

The actual number of image pixels in a scan line is specified in the support data. Following the image data more fill pixels are entered to complete the major frame. The first eight fill pixels contain the end of line code (0000 0000 7F7F 7F7F HEX), while the remainder have a value of 0)<sub>10</sub>.

The trailing 252 bits of support data in the last image minor frame are composed of 36 seven-bit words containing information associated with each image scan line. These supporting data words are described in Table 3.3-10. The third data word gives a quality code for each image scan line. The possible quality codes

ORIGINAL PAGE IS  
OF POOR QUALITY

SCAN LINE QUALITY CODE	OCTAL VALUE*	BINARY REPRESENTATION
Q <sub>0</sub> - Good quality	000	0 000 000
Q <sub>1</sub> - Not used in Landsat-D		
Q <sub>2</sub> - Filled line on input	007	0 000 111
Q <sub>3</sub> - Filled line on output	070	0 <u>111</u> <u>000</u> <div style="display: flex; justify-content: space-around; width: 100px;"> <div style="text-align: center;">             ↑ W<sub>1</sub> </div> <div style="text-align: center;">             ↑ W<sub>2</sub> </div> </div>
*Left most bit of the seven-bit scan line quality word is a "0" fill bit as shown.		

To properly detect and interpret a quality code in the presence of a one-bit error situation, the following rule is applied:

If within either W<sub>1</sub> or W<sub>2</sub> there are not three like bits, then the bit value of the majority bits within each three-bit data word is applied to reverse the binary value of the minority bit.

Figure 3.3-14. Illustrations of Quality Codes

calibration options is given in Data Format Control Book, Volume VI: Products (reference paragraph 2.2.b). The calibration wedge option was utilized by all previous Landsats. The multiplicative and additive constants which are also used in the calibration process are given in bytes 3001-3048 in the second ancillary major frame.

It should be pointed out that because of computational roundoffs and occasional dual entries in the decompression tables the radiometric calibration process is not uniquely reversible.

A fixed number of fill pixels (with a value of  $0_{10}$ ) are inserted in each major frame in front of the image pixels. The fill count is different for each band:

Band 1	75 Fill Pixels
Band 2	73 Fill Pixels
Band 3	71 Fill Pixels
Band 4	69 Fill Pixels

The actual number of image pixels in a scan line is specified in the support data. Following the image data more fill pixels are entered to complete the major frame. The first eight fill pixels contain the end of line code (0000 0000 7F7F 7F7F HEX), while the remainder have a value of  $0_{10}$ .

The trailing 252 bits of support data in the last image minor frame are composed of 36 seven-bit words containing information associated with each image scan line. These supporting data words are described in Table 3.3-10. The third data word gives a quality code for each image scan line. The possible quality codes

are illustrated in Figure 3.3-14. (Note: Although quality code  $Q_1$  was used for previous Landsats, the processing of Landsat-D and D Prime data is handled in a fashion that does not allow a code similar to  $Q_1$  to be assessed. However, to maintain the previous format, space is still reserved in the trailer data for a quality code summary count for  $Q_1$ .)

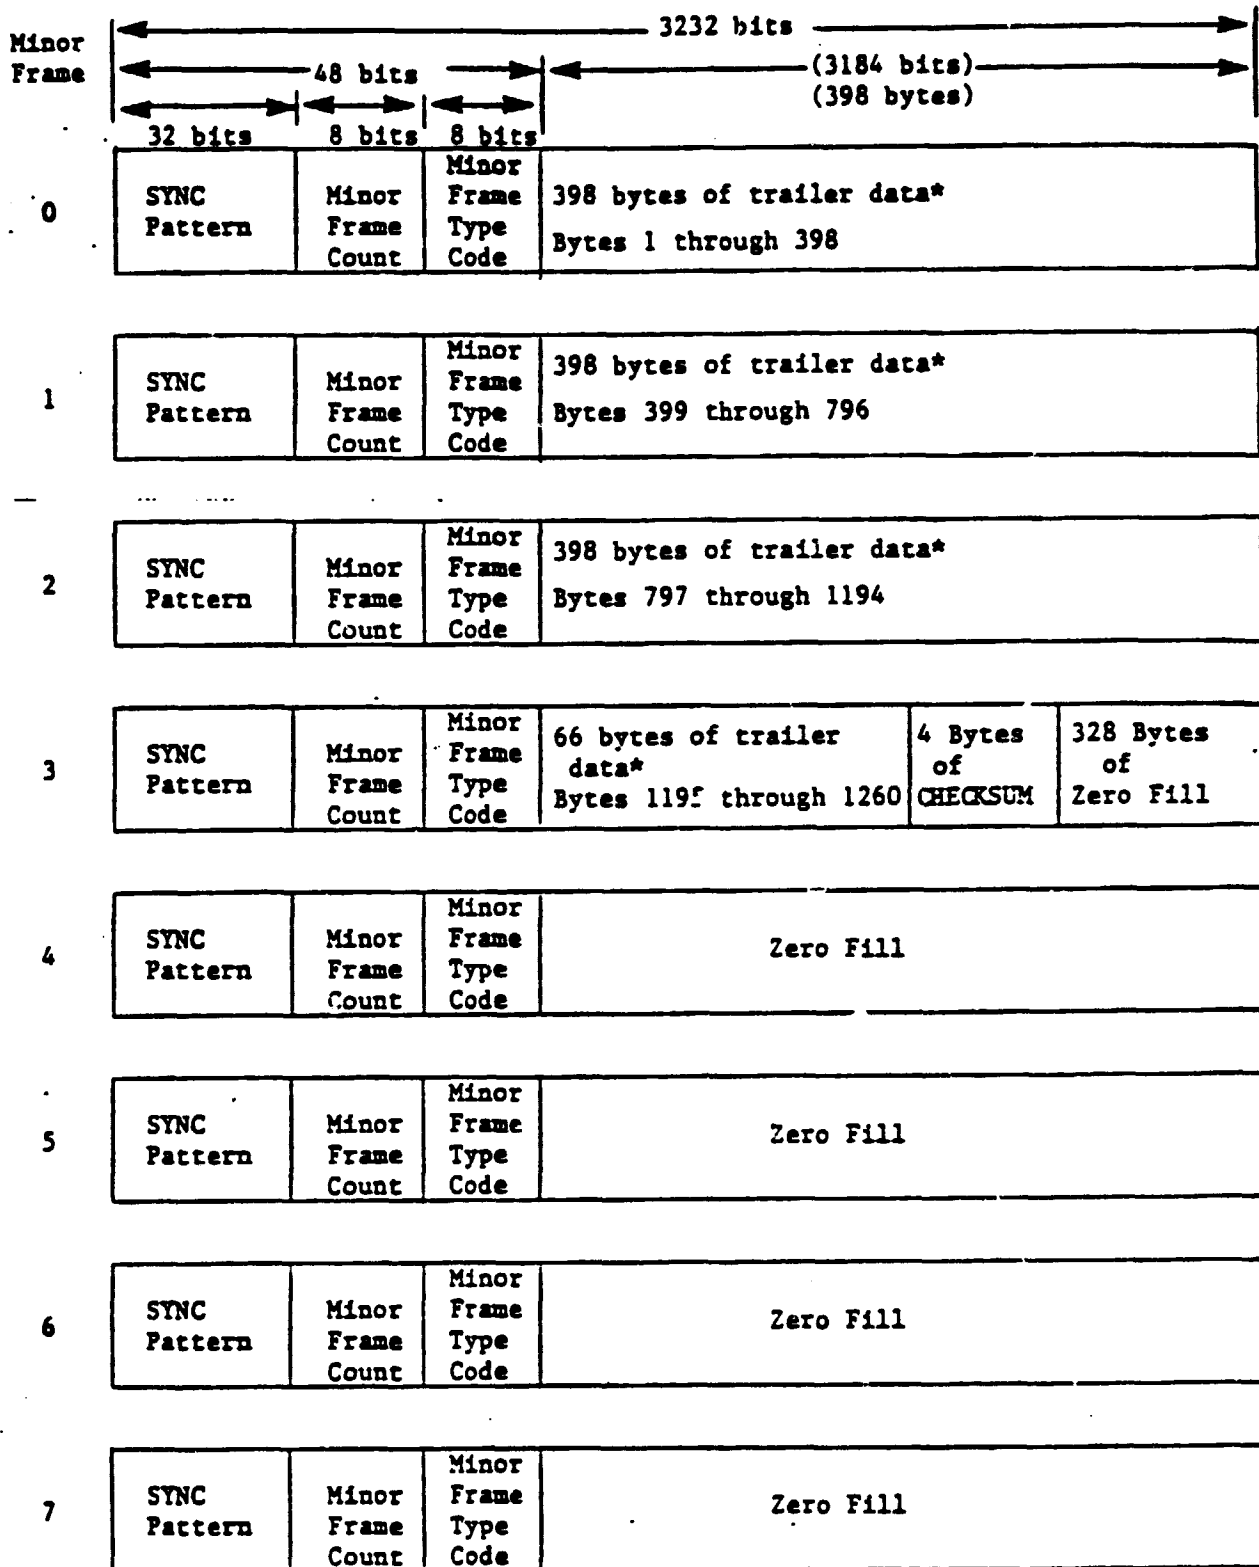

A quality condition of "good quality" -  $Q_0$  is assessed when no faults are known. A quality condition of "filled line on input" -  $Q_2$ , is assessed when the output line was synthetically filled during the data input process, e.g., due to a condition such as "sync loss". A quality condition of "filled line on output" -  $Q_3$  is assessed when the output line is synthetically generated during the data output process. In both these cases the usual result is to repeat the last line which received an assessment of  $Q_0$ .

The quality code hierarchy is ordered from most severe ( $Q_3$ ) to least severe ( $Q_0$ ). When more than one quality assessment affects the output line, the most severe assessment is assigned to the output line, i.e.,  $Q_3$  is assigned when both  $Q_2$  and  $Q_3$  occur.

### 3.3.7 TRAILER DATA

The trailer data provides counts that can be used for quality control purposes and thus gives a measure of the quality of the image data. An example of a major frame of trailer data is shown in Figure 3.3-15. The data elements that comprise the trailer data are provided in Table 3.3-11.

<u>BYTES</u>	<u>DATA</u>	
1	XXX	Flag indicating last scene (each image) in a data interval: 000) <sub>8</sub> = No 377) <sub>8</sub> = Yes
2	000	Flag indicating last scene (each image) on this reel of tape; not used, always 0
3	000	Zero Fill (not used)
4	XXX	Geometric Modeling Flag: 000) <sub>8</sub> = Precision Fit with Control Points 377) <sub>8</sub> = Systematic Fit
5-148		Inverse state covariance matrix. The inverse state covariance matrix is a 6 by 6 matrix containing statistical information about the 6 state variables; along track, across track, yaw, altitude, along track rate and across track rate errors. This will provide a measure of the quality of the geometric correction process.  The elements of the matrix are presented in the following order: Row 1, Column 1 Row 1, Column 2 Row 1, Column 3 . . . Row 1, Column 6 Row 2, Column 1 . . . Row 2, Column 6 . . . Row 6, Column 6 Each value is in the floating point format.
148-153		State vector components modeled. One byte is reserved indicating whether each of the six state vector components was modeled. An ASCII 'Y' indicates the component was modeled, and ASCII 'N' indicates it was not. The components will be in the following order: Along track error Across track error Yaw error

Table 3.3-11. Trailer Data Elements (cont'd)

<u>BYTES</u>	<u>DATA</u>
	Altitude error Along track rate error Across track rate error
154-844	Zero Fill
845-860	Quality Code Summary Counts for the image (4 counts, 4 bytes per count). Counts are in the Fixed Point Binary Format discussed in paragraph 3.2.3.4.1.
845-848	Summary Count of $Q_0$ values.  First byte = $000)_8$ , octal value of $Q_0$ ; second byte is not used; third and fourth bytes contain the total number of scan lines with this quality in the current image.
849 - 852	Summary Count of $Q_1$ values  First byte = $077)_8$ , octal value of $Q_1$ ; second byte is not used; third and fourth bytes contain the total number of scan lines with this quality in the current image
853 - 856	Summary Count of $Q_2$ values  First byte = $007)_8$ , octal value of $Q_2$ ; second byte is not used; third and fourth bytes contain the total number of scan lines with this quality in the current image.
857 - 860	Summary Count of $Q_3$ values First byte = $070)_8$ , octal value of $Q_3$ ; second byte is not used; third and fourth bytes contain the total number of scan lines with this quality in the current image.
861 - 864	Line Quality Map Word Count  $F = 377)_8$ indicates that a quality map for entire image follows (starting in byte 865) or $F = 366)_8$ indicating that a quality map for a partial image follows (starting in byte 865). Second byte is not used.  $XXXXXX$ = line quality map word summary count "N" (binary). The maximum value of "N" is $99)_{10}$ .  The line quality map contains a 4-byte entry for each group of consecutive scan lines that have the same quality assessment. "N" gives the number of these entries.

A significant difference from tapes produced for previous Landsats is that copy tapes will not contain parity count information in minor frame seven (7) of the trailer major frame. Copy tapes are identical to the original in every aspect.

#### SECTION 4

##### ABBREVIATIONS, ACRONYMS, SYMBOLS AND TERMS

Band	A collection of pixels representing a spectral portion of a scene
BIL	Band Interleaved by Line data format
BSQ	Band Sequential data format
Bit	The smallest element of binary, computer-intelligible data
Byte	A unit of data consisting of eight bits
CCT	Computer Compatible Tape
CP	Control Point
CWV	Calibration Wedge Values
Detector	A component of a sensor that is able to sense incident energy in a region of the electromagnetic spectrum
ECC	Error Correction Code
EDC	EROS Data Center
EDIPS	EDC Digital Image Processing System
EROS	Earth Resources Observation System
GCP	Geodetic Control Point
GHIT	Goddard HDT Inventory Tape
GMT	Greenwich Mean Time
GPS	Global Positioning System
GSFC	Goddard Space Flight Center

ORIGINAL PAGE IS  
OF POOR QUALITY

GSTDN	Ground Segment Tracking Data Network
HDT	High Density Digital Tape
HDT-AM	High Density Tape containing partially processed MSS data
HEX	Hexadecimal, base 16 notation
HRS	Horizontal Resampling
Interval	Set of contiguous scan line imagery comprised of one or more scenes
IGF	Image Generation Facility
IRIG-A	Inter-range Instrumentation Group standard time, format A
Landsat	Land Satellite (formerly ERTS - Earth Resources Technology Satellite)
LSB	Least Significant Bit
MFTC	Minor Frame Type Code
MIPS	MSS Image Processing Subsystem
MSB	Most Significant Bit
Pixel	One image detector sample
PS	Polar Stereographic Projection
Right Justified	Technique of positioning data so that the least significant bit appears in the rightmost position
S/C	Spacecraft
Scan Line	The data produced by one cross track motion of an active detector (a full scene width)
Scene	One or more spectral bands of data representing a 185km X 170km ground area

ORIGINAL PAGE IS  
OF POOR QUALITY

Sensor	An imaging instrument (a sensor may consist of one or more detectors)
SOM	Space Oblique Mercator Projection
Swath	The terrestrial strip viewed by the spacecraft
Sweep	One back and forth cycle of mirror movement
TDRSS	Tracking and Data Relay Satellite System
Tick Marks	Positional marks placed on imager to enable a location grid coordinate system to be constructed
TM	Thematic Mapper
UTM	Universal Transverse Mercator Projection
VRS	Vertical Resampling
WRS	World Reference System
